Abstract: *This study demonstrates for the first time how a toll gate can be fully controlled using the "Internet of Things" idea based on image processing technology. We examine and report on the circumstances of total time spent by a specific vehicle for money transaction on toll plaza and further evaluate total fuel wastage as well as human errors involvement, in reference to survey of annual toll collection on toll plazas, conducted by government in the year 2010. Finally, we agree with the idea of automating toll plazas entirely with the help of IoT technology and image processing in order to provide an ideal answer.*

Keywords: *image analysis, feature extraction, and classification, Internet of Things.*

1. INTRODUCTION

The Thomas Adams Gum Company, which sold gum on railway platforms in New York City, constructed the first vending machine in the United States in 1888. In 1897, the Pulver Manufacturing Company added small figures that would move around whenever someone bought gum from their machines. This was the first time that the concept of including games to these machines as an additional incentive to buy appeared. The "trade stimulators" are a completely new class of mechanical gadget that were born from this concept. Because there are more cars on the road today, traffic has been growing in recent years. There is an increase in traffic in developing countries as a result of millions of people choosing to use their personal cars each day rather than public transportation. In addition to congestion, air pollution, and fuel waste, an increase in the number of cars on the road causes many other issues. There are particular kinds of roadways known as toll roads where you must pay to use the road. You must pay a fee called a toll tax in order to use that route. Only drivers on toll roads are subject to the toll levy. There could, on occasion, be multiple On a specific toll road, the Toll Plaza. An expensive route is not always expensive. When building costs have been covered by toll revenue, tolls may be eliminated. The cash is collected from the driver and a receipt is given at each and every mechanically run toll booth along the highway. On crowded highways, traffic jams frequently occur at the toll plazas as a result of this procedure's potential for slowness. Toll booths do have a lot of lanes, though, to help the flow of traffic along as quickly as feasible. You can use cash or change to pay for some lanes while using express lanes requires an electronic pass that is attached to the user's car. The main driver of the country's prosperity today is transportation. Our fast-paced way of life is characterized by exceptional mobility independence, massive trade in manufactured products and services, high employment, and social movements. One could say that the nation's fiscal strength is directly correlated with its effective transportation infrastructure. Since there are more cars on the road every day, issues like traffic jams, collisions, and air pollution have grown to be significant causes for concern. To cut down on unnecessary transportation costs, every industry has its own unique way of transportation. Therefore, offering high-quality transportation will greatly boost productivity and the economy. A key element in the development of the economy and society is the decrease of transportation costs for moving raw materials to manufacturing facilities and finished goods to the consumer market. Significant difficulties include the need to cut down on traffic and travel time, improve safety, and boost productivity. As a result, one can better optimise the resources that are currently under constraint by improving system efficiency and making efficient use of contemporary technology. Toll plazas are intended to be automated by IoT toll collection systems in order to keep fairness in the transactions made during toll collections. Systems for IoT toll collection are discussed in

this literature review. When a customer inserts money or credit into a vending machine, the machine instantly dispenses things to the customer like snacks, drinks, alcohol, cigarettes, and tickets. Early in the 20th century, England created the first modern vending machines that gave out postcards. This experiment explores the significance of an Arduino-powered modern vending machine. In India, vending machines tend to only be found in large towns or along a few national highways and are not very common. The idea of vending devices was first introduced to India by Seaga India, a wholly owned subsidiary of the Seaga Group of the United States. The Delhi Metro, state and federal governments, IT farms, factories, BPOs, and other organizations use Seaga India's equipment. Snacks, drinks, condoms, bus and train passes, jewellery, and spare change are all sold by vending machines. The failure of vending machines in India has been ascribed to a number of factors. Operating shops or kiosks is cost-effective because inexpensive labour is readily available. Analysts predict that usage will increase because vending machines are still comparatively new in India.

2. RELATEDWORKS

William Vickrey was the initial proponent of the computerized toll system. For the Washington Metropolitan Area, he suggested this approach. He also won the 1959 Nobel Prize in Economics [5]. Norway was completely covered by the reader and transponder equipment. In the Bergen, the method was discussed (1986). In Trondheim, the first fully automated electronic toll collection device was unveiled (1991). Norway also uses computerized payment processing. [5] Vehicles can immediately pass through electronic toll booths in a number of locations across the United States, including California, Pennsylvania, Texas, Delaware, and Florida. Electronic toll booth procedures are quicker for the same number of vehicles because the users have already preregistered. It was possible to fit toll collecting gates into smaller, narrower roads because they are typically wider than the initial width of the road. Even though these restrictions exist, if the toll booth operation time is cut down, the speed of operation can be improved. Less total lanes were needed the faster the operation ran, and as more lanes became automated, the project's overall short-term cost decreased. Additionally, a greater proportion of vehicles began using electronic tolls, while the number of vehicles using manual tolls decreased, when the project's overall cost is taken into account. [5] Infrared sensors are to be used; it is suggested in the approach, to collect data from the trash cans in real time, and a microcontroller board to transmit that data to the waste managers. These sensors gather data from the items and their environment, then transmit it to other stations that are connected by wired or wireless networks. The system uses infrared (IR) sensors to detect when a bin is full, notifies the trash managers when a bin is full, and provides the most efficient path for collection. [10] Using RFID (Radio Frequency Identification) technology, which was only capable of item identification, tracking, and information extraction, the Internet of Things was first technically realized. By connecting actual or virtual objects to the Internet, the implemented IoT-based system, on the other hand, carries out sensing, actuating, data collecting, storing, and processing. [10] The references state that A module is suggested to make communication between RF Modems over a wireless channel easier while also facilitating car monitoring, toll collection, and reliable vehicle authentication on highways. The Base Module and the Vehicle Module (Active RFID Tag) are the two different categories of application modules. The vehicle's microcontroller holds user-specific data about the user, such as the owner's information with his billing location, the vehicle's engine number, and the vehicle's registration number. The base module gives the base module the ability to check the activities of vehicles in range, including the vehicles in range, their state, and the specifics about any registered vehicle. [6] The module's cost and the ability to purchase a module for a reduced price are two of its main benefits. With its three operating modes—active, sleep, and deep sleep—the power-saving architecture produces a device that is extremely power-efficient. Reprogramming the module will allow for simple calibration when necessary for a variety of sensing interfaces. [13] Currently, manual operation is used in the traditional toll booths. It takes a lot of time to gather tolls this way. The traditional method of collecting the toll from vehicle owners or drivers is to have them stop their cars at the toll plaza, pay the required amount to the toll collector who is located by the toll booth, and then wait for the gate to be opened either mechanically or electronically to allow them to pass through the toll station. Precious fuel is wasted as a result of these abrupt stops on roadways that appear to be well-built. One more problem has to deal with currency and even wait for change. Following payment of the toll fee When buying a two-way ticket, a document is given that must be kept. It is also possible to leave the toll booth without paying. Assume the manual toll collection method is very effective and that it takes one vehicle 50 seconds to stop and pay taxes. Now, if 200 vehicles cross the toll plaza, the time required by one vehicle with a 50-second average stop time in a month is: $50 \times 30 = 1500$ seconds; the total time required annually is: $1500 \times 12 = 18000$ seconds; and, on average, each vehicle that passes through the toll plaza must wait 5.0 hours while keeping its engine running. This number is astounding because it implies that on average, 200 vehicles travel through.

3. EXISTING SYSTEM

The procedure of separating the coins is the main issue with having a coin-operated vending machine. In our nation, there are numerous coins with the same value, which makes the segregating process challenging. Additionally, since the coin sizes are essentially the same, the gravity sorting method cannot be used. The magnetic circuit technique, which measures the current produced by a change in the magnetic field, is ineffective because the magnetic material content of Indian coins is essentially the same. Coins won't last for very long because technology is consuming the globe. Metals can be altered and become improperly differentiable.

4. PROPOSED SYSTEM

When the project was evaluated, it was determined to research the operation of similar machines. In contrast to traditional vending machines, the vending machine in use here transfers money using RFID tags. Coins or tokens are the straight payment methods used by the majority of vending machines. It is a laborious procedure that costs time and money to establish the legitimacy of the payment that was received. The string compare function is used to compare the information stored in the tags with the information stored in the tags of each user. If a match is discovered, a transaction is started. It displays the product price, the amount on your account at the moment, and the updated account balance after taking the product price out.

1. Establishing a concentrated distribution system that uses less labour.
2. Creating a simple system for distributing products that are frequently needed or wanted.
3. cutting down on the amount of labour, time, and energy used in traditional transactions.
4. Increasing the appeal of this substitute in India, where the use of vending machines is still not widely embraced.
5. Break down the complexity and create a prototype that meets the aforementioned criteria.

	Conventional Systems	RFID	FASTag	BookMyToll (as per system description)
Time Consumption	High	Average	Average	Average
Fuel wastage	High	Low	Low	Low
Traffic	High	Average	Average	Average
Payment Mode	Cash/Debit Card/Credit Card	Online	Online	Online
Processing	High	Average	Average	Average

FIGURE 1. Comparison of various systems

The person (user) must carry out the following easy tasks in order to obtain the product from the vending machine.

1. Have the ability to locate information when using a computer.
2. You need to present the customer's identification.
3. The machine shows the user's account value when it detects the tag. The user must then select the product of their choice from the available choices.
4. Press submits and waits until your selection appears.
5. The LCD then shows the new account amount.
6. Pick up the package from the dispenser.

Due to the mechanical nature of the sorter body, it was challenging to reduce the small mistakes that it produced. Accounts must be topped off by the user in person by making a cash deposit to the proprietor or at a location designated by the owner.

5. CONCLUSION

The cash is collected from the driver and a receipt is given at each and every mechanically run toll booth along the highway. We frequently experience gridlock at the toll booths on congested highways because this process can be slow. Time, effort, and energy will be saved by toll gathering that is automatic. This method, along with the automatic toll collection system, expedites toll collection and, as a result, lessens toll plaza traffic congestion. Instead, we create a system that makes toll collection quick and secure while also using image processing to autonomously regulate vehicle movement at toll stations. Before arriving at the toll booth, using an Android programme, payment can be made using mobile wallets, credit cards, or net banking. As the processing can be done straight from the video feed received through CCTV installed at the toll plaza, we wouldn't need to install any smart devices at the toll plaza if we used image

processing.

6. FUTURE WORK

For this undertaking, a credible method was found after reviewing a number of models. A explanation of the vending machine's mechanism is provided. A mobile android application can manage cloud info. The ability to register, top off, and renew a toll account will be provided through an Android programme. Additionally, this module needs to include protection system integration. Decreased costs and increased dependability will follow from the module's implementation at a higher scale.
